

GA4 + BigQuery + Webflow + Stripe

GA4, BigQuery, Webflow, and Stripe form a powerful no-code/low-code stack for tracking website analytics, form submissions, and e-commerce payments in a centralized data warehouse. This setup enables unified revenue attribution, conversion funnel analysis, and custom SQL queries across web traffic and transactions. Given your RevOps pilot focus on quick revenue metrics, this pipeline supports daily dashboards for lead-to-payment lift without heavy engineering.^[1]

Core Integrations

Link GA4 directly to BigQuery via the GA4 Admin panel for daily or streaming export of raw events like page views and custom conversions from Webflow sites. Connect Stripe to BigQuery using native Data Pipeline for automated syncing of payments, invoices, and customer data, or no-code tools like Estuary Flow for real-time events. Webflow integrates with GA4 natively via custom code embeds and supports Stripe for e-commerce checkouts or payment links, routing form data via webhooks.^{[2] [3] [4] [5] [6] [7]}

Data Flow Pipeline

- **Webflow → GA4:** Embed GA4 script in site head; track form submissions and button clicks as custom events (e.g., "add_to_cart" for Stripe links).^{[8] [9]}
- **Webflow/Stripe → GA4:** Use Stripe Checkout with GA4 parameters to pass session data through redirects, capturing funnel steps like "add_payment_info".^{[10] [11]}
- **GA4/Stripe → BigQuery:** GA4 exports events to `events_*` tables; Stripe syncs to raw tables for joins on `user_id` or `transaction_id`.^{[12] [13]}
- **Unification:** Query BigQuery to join GA4 sessions with Stripe revenue (e.g., `SELECT ga.user_pseudo_id, stripe.amount FROM ga_events JOIN stripe_payments ON ga.transaction_id = stripe.checkout.session_id`).^{[1] [3]}

Quick Setup Steps

1. Enable GA4-BigQuery link: GA4 Admin > BigQuery Linking > Select project and daily/streaming export.^[4]
2. Add GA4 to Webflow: Project Settings > Custom Code > Paste GA4 gtag.js; verify with DebugView.^{[2] [8]}
3. Connect Stripe-Webflow: Ecommerce > Payments > Connect Stripe; embed Checkout buttons.^{[5] [14]}

4. Stripe to BigQuery: Dashboard > Data Pipeline > Link BigQuery destination for ongoing syncs. [\[13\]](#) [\[7\]](#)
5. Test pipeline: Submit Webflow form → Stripe payment → Query BigQuery for joined events within 24 hours. [\[1\]](#)

Pilot Metrics Dashboard

Build a Looker Studio or BigQuery view for your 30-day revenue lift needs: track GA4 conversions (form_submit), Stripe MRR, and attribution (multi-touch via SQL). Example query flags engaged sessions with key events for power analysis. Handles your minimal ETL preference with native connectors, avoiding custom scripts. [\[3\]](#) [\[15\]](#) [\[16\]](#)

Set up GA4 to stream events into BigQuery for Webflow site

Send Webflow form submissions and CMS to BigQuery via middleware
Sync Stripe payments to BigQuery for revenue analytics
Create multi touch attribution combining GA4 Webflow and Stripe data
Best ETL tools to connect Webflow Stripe and GA4 to BigQuery

GA4 streams raw events from Webflow sites into BigQuery for near-real-time analytics, while middleware handles Webflow forms/CMS and Stripe payments sync. This enables multi-touch attribution via SQL joins on user_pseudo_id and transaction IDs. ETL tools like Estuary Flow or Airbyte provide no-code pipelines fitting your minimal-integration RevOps pilots. [\[33\]](#) [\[34\]](#) [\[35\]](#)

GA4 Streaming Setup

Enable GA4 BigQuery streaming export in Admin > BigQuery Linking: select project, data streams, and streaming option for events_intraday_* tables updated continuously. Add GA4 Measurement ID to Webflow via Project Settings > Custom Code > Head tag with gtag.js; verify events in GA4 DebugView and BigQuery within minutes. Data includes page_view, session_start, and custom Webflow events like form_submit. [\[36\]](#) [\[37\]](#) [\[38\]](#) [\[39\]](#) [\[33\]](#)

Webflow Forms/CMS to BigQuery

Use server-side middleware (Cloud Functions/Node.js) for webhooks: verify signatures, dedupe submissions, and stream to BigQuery via insertAll API. No-code options: Zapier triggers on form submits to insert rows; Airbyte/Fivetran sync CMS collections/items/assets in batches. Schema: timestamp, form_id, fields JSON, user_agent for joins with GA4 events. [\[34\]](#) [\[40\]](#) [\[36\]](#)

Stripe Payments Sync

Stripe Data Pipeline natively streams payments, subscriptions, invoices to BigQuery without ETL—connect via Dashboard > Data Pipeline > BigQuery destination. For real-time: Estuary Flow captures charges/customers/refunds with schema mapping and connected accounts support. Alternatives: Airbyte for scheduled syncs of 40+ resources. [\[35\]](#) [\[41\]](#) [\[34\]](#)

Multi-Touch Attribution

Query GA4 `events_*` joined with Stripe payments on `user_pseudo_id` or `checkout.session_id`: aggregate touchpoints (`utm_source/medium`), apply linear model (equal credit) or time-decay via SQL. Example: `WITH paths AS (SELECT user_pseudo_id, ARRAY_AGG(STRUCT(event_timestamp, traffic_source)) FROM events_* WHERE event_name IN ('page_view','purchase')) GROUP BY 1), revenue AS (SELECT user_pseudo_id, amount FROM stripe_payments) SELECT * FROM paths JOIN revenue for path analysis. Visualize in Looker Studio for channel ROI. \[42\] \[43\] \[36\]`

Best ETL Tools

Tool	Webflow	Stripe	GA4	Strengths for Your Stack	Pricing
Estuary Flow [35]	Forms/CMS via API	Real-time (40+ objects)	N/A	No-code, low-latency, fault-tolerant	Usage-based
Airbyte [34]	Full sync (forms, items)	Scheduled/full	N/A	Open-source, ELT, multi-source	Free/Cloud
Fivetran/Stitch [34]	CMS data	Payments	Native	Automated schema, scalable	Per-row
Zapier [40]	Forms webhooks	Events	Limited	Quick no-code triggers	Task-based
Stripe Data Pipeline [41]	N/A	Native streaming	N/A	Zero-setup for payments	Included

Prioritize Estuary/Airbyte for your 30-day pilots—setup in hours, handles deduping for revenue lift dashboards. [\[34\]](#) [\[35\]](#)

How to design BigQuery schema for combined GA4 Webflow and Stripe data

Example Cloud Run middleware to forward Webflow webhooks to BigQuery

How to handle webhook retries and idempotency for Webflow forms

Best practices for streaming GA4 events into BigQuery with low latency

SQL examples for multi touch attribution in BigQuery using GA4 and Stripe events

BigQuery schema design unifies GA4 events, Webflow forms/CMS, and Stripe payments via shared keys like `user_pseudo_id`, `session_id`, and idempotency fields for joins and deduplication.

Cloud Run middleware handles Webflow webhooks with retries and signature verification, streaming to BigQuery via insertAll API. SQL enables multi-touch attribution by aggregating touchpoints before revenue events. [\[54\]](#) [\[55\]](#)

Unified Schema Design

Create a unified_events table with nested STRUCT/ARRAY for flexibility:

```
CREATE TABLE `project.dataset.unified_events` (  
  event_timestamp TIMESTAMP,  
  event_name STRING,  
  user_pseudo_id STRING,  
  session_id STRING,  
  source STRING, -- 'ga4', 'webflow', 'stripe'  
  source_id STRING, -- ga4 event_id, webflow submission_id, stripe payment_id  
  idempotency_key STRING UNIQUE, -- for dedup  
  traffic_source STRUCT<source STRING, medium STRING, campaign STRING>,  
  form_data STRUCT<form_id STRING, fields JSON, page_url STRING>, -- Webflow  
  payment_data STRUCT<amount INT64, currency STRING, status STRING, customer_id STRING>,  
  revenue STRUCT<value INT64, currency STRING> -- conversions  
);
```

GA4 auto-creates events_*/events_intraday_*; partition Stripe/Webflow inserts by date for cost control. [\[56\]](#) [\[54\]](#)

Cloud Run Middleware Example

Deploy this Node.js Cloud Run service for Webflow webhooks:

```
const express = require('express');  
const {BigQuery} = require('@google-cloud/bigquery');  
const crypto = require('crypto');  
  
const app = express();  
app.use(express.json());  
  
const bq = new BigQuery();  
const WEBFLOW_SECRET = process.env.WEBFLOW_SECRET; // Verify signatures  
  
app.post('/webhook', async (req, res) => {  
  // Idempotency check  
  const idempotencyKey = req.headers['webflow-idempotency-key'] || req.body.id;  
  const existing = await bq.dataset('dataset').table('webflow_forms').row(idempotencyKey);  
  if (existing) return res.status(200).send('Duplicate');  
  
  // Signature verification  
  const signature = crypto.createHmac('sha256', WEBFLOW_SECRET).update(JSON.stringify(req)).digest('hex');  
  if (req.headers['webflow-signature'] !== `sha256=${signature}`) return res.status(401).send('Invalid signature');  
  
  // Stream to BigQuery (retries handled by Cloud Run)  
  await bq.dataset('dataset').table('unified_events').insert({  
    event_timestamp: new Date(),  
    event_name: 'form_submit',  
    user_pseudo_id: req.body.user_pseudo_id,  
    session_id: req.body.session_id,  
    source: req.body.source,  
    source_id: req.body.source_id,  
    idempotency_key: idempotencyKey,  
    traffic_source: req.body.traffic_source,  
    form_data: req.body.form_data,  
    payment_data: req.body.payment_data,  
    revenue: req.body.revenue  
  });  
  return res.status(200).send('Success');  
});
```

```

    source: 'webflow',
    idempotency_key: idempotencyKey,
    form_data: {form_id: req.body.form_id, fields: req.body.fields},
    // Add GA4 params if passed via hidden fields
  });

  res.status(200).send('OK');
});

```

Handles 3 retries from Webflow with exponential backoff; use idempotency_key for exactly-once semantics. [\[57\]](#) [\[54\]](#)

Webhook Retries & Idempotency

Webflow retries failed deliveries up to 3 times without ordering guarantees—respond 2xx within timeout or risk duplicates. Use webflow-idempotency-key header or payload id as BigQuery unique key; query before insert: `SELECT COUNT(*) FROM unified_events WHERE idempotency_key = @key`. Dead letter queue via Cloud Run logs for failed inserts after 3 attempts. [\[58\]](#) [\[54\]](#) [\[57\]](#)

GA4 Streaming Best Practices

Enable streaming in GA4 Admin > BigQuery Linking > Streaming export for events_intraday_* tables (seconds latency vs. daily 72hr lag). Limit columns in queries (`SELECT event_name, user_pseudo_id, traffic_source.name`), partition by `_TABLE_SUFFIX`, use clustered tables on `user_pseudo_id`. Costs ~\$0.01/day for 200K events; query dynamic ranges like `WHERE _TABLE_SUFFIX BETWEEN FORMAT_DATE('%Y%m%d', DATE_SUB(CURRENT_DATE(), INTERVAL 5 DAY)) AND FORMAT_DATE('%Y%m%d', CURRENT_DATE())`. [\[59\]](#) [\[60\]](#)

Multi-Touch SQL Examples

Linear Attribution (equal credit per touch):

```

WITH paths AS (
  SELECT
    user_pseudo_id,
    ARRAY_AGG(STRUCT(event_timestamp, traffic_source.name AS channel))
      OVER (PARTITION BY user_pseudo_id ORDER BY event_timestamp ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) AS touchpath,
    revenue.value
  FROM `ga4.events_*` e
  LEFT JOIN `dataset.stripe_payments` s ON e.user_pseudo_id = s.user_pseudo_id
  WHERE event_name IN ('page_view', 'purchase')
  AND _TABLE_SUFFIX BETWEEN ... -- dynamic range
)
SELECT
  channel,
  SUM(revenue / ARRAY_LENGTH(touchpath)) AS attributed_revenue
FROM paths, UNNEST(touchpath)
GROUP BY channel;

```

Time-Decay (recent touches weighted more):

```
WITH weighted AS (
  SELECT *,
    EXP((TIMESTAMP_DIFF(event_timestamp, MAX(event_timestamp) OVER(PARTITION BY user_pseudo_id
    FROM paths
  )
  SELECT channel, SUM(revenue * decay_weight / SUM(decay_weight)) FROM weighted, UNNEST(touchpoints))
```

Joins GA4 traffic_source with Stripe revenue; extend for Webflow form touches via source='webflow'. [\[55\]](#) [\[61\]](#)

✱✱

Map common identifiers across GA4 Webflow and Stripe for attribution

Design a unified event schema for sessions users and transactions

Example BigQuery table partitioning and clustering for event data

Cloud Run webhook handler code snippet in Nodejs for Webflow forms

How to implement idempotency keys for webhook deliveries at scale

Common identifiers like user_pseudo_id (GA4), Webflow visitor_id/form email, and Stripe customer_id enable cross-source attribution via hidden form fields and checkout params. A unified event schema uses nested structs with these keys for SQL joins. Partition by date and cluster on user/session IDs for query performance at scale. [\[74\]](#) [\[75\]](#)

Identifier Mapping

Pass GA4 identifiers to Webflow/Stripe via hidden form fields and URL params:

- **GA4 → Webflow:** Custom event pushes gtag('event', 'form_submit', {user_pseudo_id: '{{clientId}}', session_id: '{{sessionId}}'}); capture in form hidden fields. [\[74\]](#)
- **Webflow → Stripe:** Embed GA4 params in Stripe Checkout client_reference_id and metadata: {ga_user_id: '{{clientId}}'}. [\[76\]](#)
- **Unified Keys:** user_pseudo_id (GA4 client_id), email_hash (SHA256 of email), session_id, transaction_id (Stripe checkout.session_id). [\[75\]](#)
- **Join Logic:** LEFT JOIN webflow_forms wf ON ga.user_pseudo_id = wf.ga_user_pseudo_id OR SHA256(wf.email) = SHA256(ga.user_email). [\[74\]](#)

Unified Event Schema

```
CREATE TABLE `project.dataset.unified_events` (
  event_timestamp TIMESTAMP,
  event_name STRING,
  identifiers STRUCT<
    user_pseudo_id STRING, -- GA4 client_id
    session_id STRING,
    email_hash STRING,      -- SHA256(email)
```

```

    customer_id STRING,      -- Stripe
    visitor_id STRING        -- Webflow
>,
source STRING,  -- 'ga4', 'webflow', 'stripe'
traffic_source STRUCT<source, medium, campaign>,
form_data STRUCT<form_id STRING, fields JSON>,
ecommerce STRUCT<transaction_id STRING, revenue FLOAT64, items ARRAY<STRUCT<name STRING
_PARTITIONTIME TIMESTAMP -- Auto-partitioning
)
PARTITION BY DATE(event_timestamp)
CLUSTER BY identifiers.user_pseudo_id, identifiers.session_id;

```

Supports GA4 ecommerce schema + custom Webflow/Stripe fields. [\[77\]](#)

Partitioning & Clustering

```

-- Daily partitioning + clustering (10x query speedup)
CREATE TABLE `dataset.unified_events`
PARTITION BY DATE(event_timestamp)
CLUSTER BY identifiers.user_pseudo_id, identifiers.session_id, event_name
AS SELECT * FROM `raw_events`;

-- Query example (prunes 95% partitions)
SELECT * FROM `unified_events`
WHERE DATE(event_timestamp) BETWEEN '2025-12-20' AND '2025-12-27'
  AND identifiers.user_pseudo_id = 'abc123'
  AND event_name IN ('form_submit', 'purchase');

```

Costs drop 80% on scans; clustering auto-maintained. [\[77\]](#)

Cloud Run Webhook Handler

```

const express = require('express');
const {BigQuery} = require('@google-cloud/bigquery');
const crypto = require('crypto');

const app = express();
app.use(express.raw({type: 'application/json'})); // Signature verification

const bq = new BigQuery();
const WEBFLOW_SECRET = process.env.WEBFLOW_SECRET;

app.post('/webflow-webhook', async (req, res) => {
  try {
    // 1. Signature verification
    const signature = `sha256=${crypto.createHmac('sha256', WEBFLOW_SECRET)
      .update(req.body).digest('hex')}`;
    if (req.get('Webflow-Signature') !== signature) {
      return res.status(401).send('Invalid signature');
    }

    const payload = JSON.parse(req.body);
    const idempotencyKey = payload.id || payload.meta.id; // Webflow form/submission ID
  }

```

```

// 2. Idempotency check (at-least-once → exactly-once)
const [rows] = await bq.query(`
  SELECT 1 FROM \`dataset.unified_events\`
  WHERE identifiers.visitor_id = @idempotencyKey
  LIMIT 1`, {params: {idempotencyKey}});

if (rows.length > 0) return res.status(200).json({status: 'duplicate'});

// 3. Extract identifiers (from GA4 hidden fields)
const gaData = payload.fields.find(f => f.name === 'ga_user_pseudo_id')?.value;

// 4. Insert with structured data
await bq.dataset('dataset').table('unified_events').insert({
  event_timestamp: new Date(),
  event_name: 'webflow_form_submit',
  identifiers: {
    user_pseudo_id: gaData,
    visitor_id: idempotencyKey,
    email_hash: crypto.createHash('sha256').update(payload.email || '').digest('hex')
  },
  source: 'webflow',
  form_data: {form_id: payload.form_id, fields: payload.fields}
});

res.status(200).json({status: 'received'});
} catch (error) {
  console.error(error);
  res.status(500).send('Internal error'); // Triggers Webflow retry
}
});

const port = process.env.PORT || 8080;
app.listen(port, () => console.log(`Webhook handler on port ${port}`));

```

Deploy: `gcloud run deploy webflow-webhook --source . --allow-unauthenticated`.^[78] ^[76]

Idempotency at Scale

- **Key Generation:** Use Webflow `payload.id` + timestamp hash: `SHA256(payload.id + event_timestamp)`.
- **Check-Insert Pattern:** `SELECT COUNT(*) WHERE idempotency_key = @key LIMIT 1; INSERT IF 0.`
- **Distributed Locks:** Redis `SETNX` for 5min TTL during high-volume bursts (10K+ webhooks/min).
- **Dead Letter Queue:** Cloud Pub/Sub for failed inserts after 3 retries; process asynchronously.
- **Query Optimization:** Index `idempotency_key` or partition DLQ by date; BigQuery handles 1M+ upserts/sec.^[79]
Use transactions for check-insert atomicity in Cloud SQL if >100K events/hour.^[78]
